Falls, Gait and Balance Disorders in Older Adults:
Assessment and Interventions, May 26
Arvind Modawal, MD, MPH, AGSF, FAAFP
Rochelle McLaughlin, MS, OTR/L

Link to Handouts

This project is/was supported by funds from the Bureau of Health Professions (BHPr), Health Resources and Services Administration (HRSA), Department of Health and Human Services (DHHS) under U68HP16648, grant title: Geriatrics Education Centers, total award amount: $384,525. This information or content and conclusions are those of the author and should not be construed as the official position or policy of, nor should any endorsements be inferred by the BHPr, HRSA, DHHS or the U.S. Government.

Natividad Medical Center CME Committee Planner Disclosure Statements:
The following members of the CME Committee have indicated they have no conflicts of interest to disclose to the learners: Kathryn Rios, M.D.; Valerie Barnes, M.D.; Anthony Galicia, M.D.; Sandra G. Raff, R.N.; Sue Lindeman; Janet Bruman; Jane Finney; Tami Robertson; Judy Hyle, CCMEP; Christina Mourad and Kevin Williams.

Stanford Geriatric Education Center Webinar Series Planner Disclosure Statements:
The following members of the Stanford Geriatric Education Center Webinar Series Committee have indicated they have no conflicts of interest to disclose to the learners: Gwen Yeo, Ph.D. and John Beleutz, MPH.

Faculty Disclosure Statement:
As part of our commercial guidelines, we are required to disclose if faculty have any affiliations or financial arrangements with any corporate organization relating to this presentation. Dr. Modawal and Ms. McLaughlin have indicated they have no conflicts of interest to disclose to the learners, relative to this topic.

Dr. Modawal and Ms. McLaughlin will inform you if they discuss anything off-label or currently under scientific research.
About the Presenters

Arvind Modawal, MD, MPH, AGSF, FAAFP

Arvind Modawal, MD, MPH, AGSF, FAAFP, MRCGP, DTM&H is a board certified Geriatrician and Professor of Clinical Family and Community Medicine at the University of Cincinnati College of Medicine. He also received board certification in Hospice and Palliative Medicine in 2010.

He is currently working as a hospitalist at West Chester Hospital in Ohio and also provides patient care in Skilled nursing facilities and Assisted living facilities. He is medical director and program leader for Cincinnati region with IPC, the Hospitalist Company.

He received both graduate medical and post graduate MD degree in Internal Medicine in India and subsequently did residency training in both Internal Medicine and Family Medicine (General Practice) in the United Kingdom. He completed two-year fellowship training in Geriatric Medicine at University of Cincinnati academic health center in 1996. He is Associate Director of University of Cincinnati/ Reynolds Physician Training Center for Geriatrics. He has held several medical directorships of nursing homes, assisted living facilities, palliative care and hospice programs and a managed care organization. He has been in clinical practice for many years practicing consultative geriatric medicine, palliative care and primary care in many outpatient and inpatient settings.

He is a fellow of the American Geriatrics Society, American Academy of Family Medicine, member of American Academy of Hospice and Palliative Medicine, fellow of Geriatrics Society of India and also member of a Royal college in London, United Kingdom. He is an alumnus of Harvard University and obtained a master’s degree (MPH) in Clinical Effectiveness from Harvard University School of Public Health in 1999. He is on the board of Ohio Medical Directors Association and past president of Ohio Geriatrics Society and serves on committees of various organizations.

He has research and academic interest in falls and balance disorders, chronic complex disease management in the elderly, dementia care, geriatric assessments, palliative care, pain management, quality improvement and health informatics. He is active in direct patient care, education, research and administration.

About the Presenters

Rochelle McLaughlin, MS, OTR/L

Rochelle McLaughlin, MS, OTR/L earned a Master of Science in Occupational Therapy from San Jose State University. Her clinical specialty is in the area of traumatic brain injury, stroke, and cognitive impairment as well as working with the geriatric population in a variety of settings including Stanford Hospital’s community fall prevention program called Farewell to Falls where she has developed a Mindfulness in Fall Prevention component to the program.

Rochelle is a faculty member of the Occupational Therapy Department at SJSU where she developed and taught the Occupational Therapy in Geriatric Practice Course and more recently the Mindfulness-Based Occupational Therapy Course. Rochelle has completed advanced studies in Humanistic Psychology and is a certified yoga instructor. Rochelle teaches Mindfulness-Based Occupational Therapy (MBOT) at the Bay Area Pain and Wellness Center in Los Gatos. She is a co-author of the Adjustment to Disability chapter in Umphred’s latest edition of the Neurological Rehabilitation textbook, she is an author of numerous other publications and is doing extensive research in the area of Mindfulness and Occupational Therapy.
Falls, Gait and Balance Disorders in Older Adults

Geriatrics and Palliative Care
University of Cincinnati College of Medicine
modawaa@uc.edu

Definition of a ‘Fall’

• Anyone inadvertently coming to rest on the ground or a lower level in the absence of trauma and other overwhelming medical event (stroke, syncope) and known loss of consciousness
Falls related statistics

- 5.8 million of U.S. adults (16%) >65 yr old report a fall in previous month and 33% in previous year.
- More frequent with advancing age and among Nursing homes residents (1.6 falls/bed/year)
- Mostly minor injuries, 10-15% of falls result in fracture, and 5% in serious soft tissue injury or head trauma
- Leading cause (75%) of injury deaths for >65 yr
- Account for 87% of all fractures in over 65-year
- About 340,000 hospital admissions for hip fractures
- 60% of fatal falls happen at home, 30% in public places and 10% in institutions
- 10–25% NH falls result in ER visits/hospital care

CDC, GRS7

Nursing Home Falls

- 1.6 Falls per resident bed per year
- 2 – 3 times greater than the community
- 50% of all nursing home residents fall each year
- History of falls in the last 6-months is a risk factor for future falls
- Major liability concerns
- Requires a system-based approach to preventing and reducing falls

Rubenstein 2002, Ray 2005
Overview of causes for falls

• 1/3 - Intrinsic risk factors (medical and age-related factors)

• 1/3 - Medications, alcohol use and OTC products

• 1/3 - Extrinsic risk factors (environmental)

Falls: Intrinsic Risk factors

• Increasing Age >80 y
• History of Falls
• Female gender
• Medical Illness
• Peripheral Neuropathy
• Dizziness
• Orthostasis
• Cognitive impairment
• Visual Impairment

• Decreased muscle strength
• Abnormal gait/mobility
• Incontinence
• Depression
• Foot problems
• Hearing impairment
• Arthritis
• Diabetes
• Pain

Colon-Emeric 2001, Tinetti 2010
Falls - Extrinsic Risk Factors

Medications

- **Anticholinergics** – consider total anticholingeric load
- **Neuropsychiatric** – benzodiazepines, neuroleptics, antidepressants, anticonvulsants, antiparkinson, muscle relaxants, analgesics
- **Cardiovascular** – antihypertensives, antiarrythmics (type 1 A), digoxin, nitrates
- **Alcohol**
- **Histamine (H2) blockers** – cimetidine
- **Over-the-Counter** – cough / cold remedies, sedatives, antihistamines

CNS active medications and Falls

- **Benzodiazepines** (1.51) MOR
  - Short acting (1.42)
  - Long acting (1.56)
- **Antidepressants** (1.54)
  - SSRIs (3.45)
  - TCA (1.28)
- **Anticonvulsants** (2.56)
- **Narcotics** (0.99)
Falls: Extrinsic factors

*Environment*

- Indoor hazards – slippery floors, rugs/carpet, poor lighting, shoes, bathroom fixtures, height of chair and bed, unstable furniture, stairways.
- Outdoor hazards – uneven pavement, steps, snow and ice.

Nevitt 1989, Gill 1999

---

**Relevant Clinical Approach**

- **NOT** WHAT DISEASE caused the problem? based on one disease/diagnosis Model
- **BUT** WHAT COMBINATION of Physiologic changes, impairments and diseases are contributing?
- **AND** WHICH ONES can be modified? (Multifactorial/multicomponent assessment and Intervention Model)

Clinical Practice Guidelines
AGS/BGS 2009
Assessment of a faller

• TALK
  – Ask for history of falls every 6-months

• WALK
  – Gait and Balance disorder or both
  – Developing an approach for recurrent falls

Fall Mnemonic

S Symptoms
P Previous falls
L Location
A Activity
T Time: time of day or night
T Trauma
Timed ‘Up and Go’ Test

- Simple test of observing a person stand up from a chair, walk 10 feet, turn around, walk back, and sit down again.
- Correlates with ADLs
- Normal person takes < 10 seconds to complete the task
- Note: use of hands, staggering, unsteadiness
- Sensitivity, 54-87%; Specificity 74-87%

Podsiadlo 1991
Functional Reach Test

- Measures forward and lateral balance; Sensitive to change over time
- Simple to administer
  - Arm extension with 90 degrees of shoulder flexion while patient is upright and leaning forward or sideways
- Results
  - < 6 inches related to falls
  - Minimal fall risk if >10 inches of reach

Duncan 1990
Functional Reach test

- Test for proprioception primarily to differentiate sensory ataxia (central and peripheral) from cerebellar ataxia
- Sharpened Romberg’s may be helpful in the elderly

Romberg’s test

- Test for proprioception primarily to differentiate sensory ataxia (central and peripheral) from cerebellar ataxia
- Sharpened Romberg’s may be helpful in the elderly
Sharpened Romberg’s

Feet together  Semi-tandem  Tandem

Balance (Sharpened Romberg test). Patient stands with feet together, semi-tandem, and tandem, with eyes open for 10 seconds then closed for 10 seconds in each position.

Single leg stance test

• Best balance measure for any individual
• If one can stay on one leg for 10 seconds, there are usually no significant balance problems

Bohannon 1984, Janda 1996
Modified Single leg Stance

Hip abductors. Patient stands behind back of chair and—while using fingertips for light support—slowly lifts one leg for 5 seconds. Repeat for other leg. Pelvis drop on non-weight-bearing side indicates muscle weakness.
Fracture and fall dynamics

- Fall
- Fracture
- Force
- Fragility

Prevention

- Calcium (at least 600mg)
- Vitamin D (800 I.U.) daily
- Bisphosphonates, if tolerated
- Miacalcin spray
- Others
Hip Protectors

- Trochantric (hip) padding can decrease the chances of hip fracture after a fall
- Hip fracture reduction in few trials
- Compliance remains a problem
- Cost issues and evidence mixed, but worth considering in ‘high-risk’ individuals
- Design issues - one with hard ‘inserts’ vs. foam padding!

Parker MJ 2001, VanSchoor NM 2003
Multifactorial/multicomponent interventions to prevent falls

- Minimize medications
- Individually tailored exercise program
- Treat vision impairment (cataracts)
- Manage postural hypotension
- Manage heart rate and rhythm changes
- Supplement Vitamin D
- Manage foot and footwear problems
- Modify home environment
- Provide education and information

Clinical Practice Guidelines
AGS/BGS 2009
Summary

- Falls are a significant cause of morbidity and mortality in the elderly
- Falls in the elderly are multifactorial
- Individualized multicomponent and multidisciplinary intervention approaches provide the best evidence for prevention and management.

Falls, Gait and Balance Disorders in Older Adults

Part II

Community-Based & in-home Fall Prevention Assessment, interventions, & follow-up

Rochelle McLaughlin, MS, OTR/L, MBSR
Department of Occupational Therapy
San Jose State University
Stanford Farewell to Falls
Bay Area Pain and Wellness Center
www.rochellemclaughlin.com
rochelle.mclaughlin@sjsu.edu
Community-Based Fall Prevention

- Reaching older adults that may not have access to knowledge otherwise
- Ability to reach larger number of older adults in lecture format
- Sense of community and group participation can be of great benefit and provide much needed social support
- Follow through may be a challenge

In-Home Fall Prevention

- Able to observe individual in their own environment
- Able to practice learned skills in real time & functional, meaningful way
- Able to reach populations that have less access to community-based programs
- May be more compliance with programs taught in the individual’s home
Assessment

- Consent forms
- Fall History - does not need to have had a fall
- General Medical History
- Medications
- Fall risk assessment
- Home assessment

Fall History

- Date of most recent fall
- Number of falls in past year
- Description of fall, location, was medical treatment needed
- Fear of falling?
- Assistive device used
General Medical History

- Health interview
- Highlighting any area that may increase the risk of falling
  - Physiological
  - Cognitive
  - Psychological

Activities of Daily Living and Exercise

- Identifying a baseline level of functioning
- ADL tolerance
- Exercise tolerance
Medication Review

- Many older adults do not know that prescription drugs can increase their risk of falling
- Common side effects:
  - Dizziness, lightheadedness, nausea
  - Fatigue, weakness
  - Some can effect electrolyte balance

Gait & Balance Assessment

- Gait test
- Balance test
  - Used as an educational tool
  - Highlights areas aging adult can improve
Intervention

- Mindfulness in fall prevention
- Home recommendations
- Medication review, side effect education
- Exercise education
- Nutrition & hydration education if appropriate

Mindfulness in Fall Prevention

- Pause when changing position
- S.T.O.P
- Awareness of body sensations
- Awareness of sensation of breath
- Slow down
- Pay attention to task at hand
  - While walking pay attention to the act of walking...
Home Safety Assessment

- Entrances and exits: railings, lighting, surfaces
- Floors: clutter, cords, rugs removed or stapled down, smooth surfaces
- Shower/tub: grab bars, non-slip mats, outlets
- Bedroom: lamp & phone within reach of bed

Home Safety Assessment

- Kitchen: safe step stool use, refrigerator opens easily, non-slip mats
- Shoes: thin, rubber-soled shoes recommended
- Stairs: railings run full length of stairs, ideally both sides, well-lighted
- Emergency phone numbers posted, vial of life, Lifeline
Exercise recommendations

- Physician referral required to talk to participant about exercise:

- Why 5?
  - Strength
  - Balance
  - Flexibility
  - Endurance
  - Walking

Strength
If you have trouble getting down on or up from the floor by yourself, try using the buddy system. Find someone who will be able to help you. Knowing how to use a chair to get down on the floor and get back up again also may be helpful. If you've had hip or back surgery, talk with your doctor before trying it.
Endurance

How to Improve Your Endurance

Endurance exercises:
- Walking, jogging, swimming, raking, sweeping, dancing, playing tennis
- Increase heart rate and breathing for an extended period of time.

Counting Your Steps

- Step counters help track endurance activity, set goals, and measure progress. Most inactive people get fewer than 5,000 steps a day, and some very inactive people get only 2,000 steps a day.
- Fewer than 5,000 steps a day, gradually try to add 3,000 to 4,000 more steps a day.
- About 8,000 steps a day, you’re probably meeting the recommended activity target.
- 10,000 or more steps a day, you can be confident that you’re getting an adequate amount of exercise.

The Big Four

- In an attempt to increase compliance with exercise recommendations keeping it simple appears to be critical
  - Ankle Circles
  - Ta-Da
  - Side step
  - Sit to stand
Follow-Up

- Participants are called every two weeks
- Answer questions
- Help provide motivation for exercises, Participant refers to calendar handout

1-year Follow-up Visit in the home
- Balance and gait re-assessment
- Go over any interventions that may need to be highlighted

A Matter of Balance: Managing Concerns About Falls
http://www.thompsonfitnesssolutions.com/meet_christian.html
OFFICE VISIT FORM: FALLS/MOBILITY PROBLEMS

Reason for Visit:  
☐ Fall since last visit (or in last year, if new patient)  
☐ Fear of falling, balance/trouble walking

History of Present Illness:
1. If patient fell, date of last fall: __________________
2. Circumstances of fall: 
   - YES  NO  
   - Cane……………………………………….. 
   - Loss of consciousness………………….. 
   - Tripped/stumbled over something……. 
   - Wheelchair………………………………… 
   - Light-headedness/dizziness…………. 
   - Unable or needed assistance to get up 
   - Pattern similar to previous falls……… 
3. Psychotropic or medications (specify): 
   - Neuroleptics: ____________________ 
   - Benzodiazepines: ________________ 
   - Antidepressants: ________________ 
   - Other med changes ______________ 
4. 2 or more drinks alcohol each day........ 
5. Uses device for mobility: 
   - YES  NO  
   - Cane……………………………………….. 
   - Walker…………………………………….... 
   - Wheelchair………………………………… 
   - Other, specify: ______________________ 
6. Other conditions (e.g., Parkinson's, CVA, cardiac, neuropathy, severe OA), specify: 
7. Vision: 
   - Notice recent vision change…………. 
   - Eye exam in past year………………….. 
8. Hearing:  Impaired / Normal…

Examination:
1. Lying:  
   - BP: _____/_____ 
   - Pulse: _____ 
2. If NO eye exam in past year, Visual Acuity: OS: 20/_____ 
   - Corrected 
   - OD: 20/_____ 
   - OU: 20/_____ 
3. Cognition:  
   - 3-Item recall: ☐ PASS ☐ FAIL If FAIL ➔ Cognitive status:
4. Gait:  ☐ NORMAL ☐ ABNORMAL 
   Abnormal: ‘Timed Get up and go test’ if:-Hesitant start 
   -Hips do not clear floor or toes of other foot 
   -Broad-based gait 
   -Extended arms 
   -Path deviates 
   -Time >10 secs
5. Balance:  
   - YES NO  
   - Side-by-side, stable 10 sec….. 
   - Semi-tandem, stable 10 sec.. 
   - Full tandem, stable 10 sec..... 
   - If indicated: 
     - Single leg stance 10 secs .............. 
     - Romberg's Eyes closed, nudge .... 
     - Time >10 secs 
6. Neuromuscular Strength:  
   - Quad strength: Can rise from chair w/o using arms……….
   - If indicated, hip ROM and knee exam: 
   - Upper Extremity function: Normal Grip ………. 
   - Touch top of head and back……………….

Diagnosis/Treatment Plan:
Lab/Tests:  
☐ Blood tests  
☐ Urine A and C/S  
☐ X-rays chest  
☐ EKG/ Holter monitoring  
☐ CT/MRI  
☐ X-rays Injury - Fracture site
Impression:  
☐ Strength problem  
☐ Balance problem  
☐ Gait disorder  
☐ Visual Impairment  
☐ Hip/knee OA  
☐ Orthostatic hypotension  
☐ Other___________  
☐ Parkinsonism  
☐ Anxiety/depression  
☐ Vestibular disorder  
☐ Medication issue
Treatment:  
☐ Patient education handout: 
  - “Falls”  
  - “Home safety checklist”  
  - Strength/balance exercises: 
    - Upper body  Lower body 
  - Community resources  
  - Personal or Community exercise program  
  - Other: 
☐ Referral for PT  
☐ Assistive device:  
☐ Referral for OT home safety inspection/modifications  
☐ Change in medication(s):  
☐ Referral for eye exam  
☐ Cardiology consult  
☐ Neurology consult  
☐ Other: ____________________________________

Date of Birth: ___________________________
Take Home message: “7-steps” to take for elderly fallers

1. Falls in the elderly are a marker for ‘acute medical event’, therefore one has to be aware of multi-factorial risk factors for falling. Investigate for infections, medication side-effects, and metabolic problems. Falls associated with loss of consciousness (syncope) suggests cardiovascular etiology.

2. Evaluate role of multiple medication use including OTC products, medication dose adjustment or withdrawal and side-effects in people who fall. (CNS, Cardiovascular, warfarin and INR)

3. Meticulous history with structured assessment of gait and balance, orthostatic hypotension, muscle strength, vision and hearing is essential. Check Romberg’s, Timed ‘get up & Go’ test, Functional reach and Single leg stance.

4. Home/Environmental safety assessment should be done with consideration for assistive devices. Pay attention to shoes, lights and flooring.

5. Interventions for strength and balance training can decrease the risk of falling. Timely Physical and Occupational therapy may help. Increase regular physical activity.

6. Osteoporosis prevention and use of protective devices (hip protectors) reduce fractures, particularly hip. Calcium and Vitamin D supplementation for all.

7. Understand the significance of ‘fear of falling’ in the older adults and its impact on mobility and functional status, hence counseling and encouragement of activity and routine exercises is desirable.
The Patient Who Falls
“It’s Always a Trade-off”

Mary E. Tinetti, MD
Chandrika Kumar, MD

The Patient’s Story
Mr Y, an 89-year-old retired salesman, lived independently until 3 years ago. He had a right humeral fracture in 2006 and a left hip fracture 3 months later. After hip fracture repair and rehabilitation, he moved in with his daughter, a physical therapist.

Mr Y’s medical history includes coronary artery bypass grafting and porcine aortic valve replacement in 2003; dementia; hypertension; gout; peptic ulcer disease; macular degeneration; and bilateral hearing aids. In 1992, Mr Y fractured his right hip in a bar brawl; he used alcohol heavily until a few years ago.

On arrival at his daughter’s home, Mr Y reported left hip pain and an unsteady gait. He became delirious when taking oxycodone ER, 10 mg every 12 hours. In June 2007, his daughter brought Mr Y to see Dr C, a geriatrician, who noted pruritus, chronic rhinorrhea, and weight loss. Mr Y scored 28 of 30 on the Folstein Mini-Mental State Examination; he missed the date and recalled 2 of 3 objects at 5 minutes. Mr Y’s recall of 2 words, plus his abnormal clock drawing (eFigure, available at http://www.jama.com), indicated a positive screen for dementia.2,3 Mr Y denied depressed mood or loss of interest with the 2-item depression screen.4 He was independent in his basic activities of daily living (ADL) but dependent in his instrumental ADL (TABLE 1, footnote f).5,6 His medications included aspirin, 81 mg; metoprolol XR, 100 mg; lisinopril, 40 mg; hydrochlorothiazide, 12.5 mg; simvastatin, 20 mg; omeprazole, 20 mg twice a day; allopurinol, 100 mg; acetaminophen/hydrocodone, 1 tablet as needed; docusate, 250 mg twice a day; and nitroglycerin, 0.4 mg sublingually for chest pain.

Mr Y’s blood pressure was 148/61 mm Hg without orthostatic changes. He weighed 158 lb. A grade 3/6 systolic ejection murmur was present without signs of heart failure. Mr Y’s strength and sensation were normal except for left hip and knee weakness. There was tenderness to palpation over the left greater trochanteric region; the hardware from his hip surgery was palpable. The Romberg test result was negative. A mobility screen (with Mr Y’s results) is shown in the Box.7

Results of urinalysis, complete blood cell count, and routine serum chemistries were normal. A left hip radiograph revealed nonunion and bony collapse. A magnetic resonance imaging scan of the brain revealed multiple infarcts.

See also p 273 and Patient Page.

Falls are common health events that cause discomfort and disability for older adults and stress for caregivers. Using the case of an older man who has experienced multiple falls and a hip fracture, this article, which focuses on community-living older adults, addresses the consequences and etiology of falls; summarizes the evidence on predisposing factors and effective interventions; and discusses how to translate this evidence into patient care. Previous falls; strength, gait, and balance impairments; and medications are the strongest risk factors for falling. Effective single interventions include exercise and physical therapy, cataract surgery, and medication reduction. Evidence suggests that the most effective strategy for reducing the rate of falling in community-living older adults may be intervening on multiple risk factors. Vitamin D has the strongest clinical trial evidence of benefit for preventing fractures among older men at risk. Issues involved in incorporating these evidence-based fall prevention interventions into outpatient practice are discussed, as are the trade-offs inherent in managing older patients at risk of falling. While challenges and barriers exist, fall prevention strategies can be incorporated into clinical practice.
hydramine. Another fall occurred in July 2008 after he inadvertently took several sublingual nitroglycerin tablets and developed dizziness and headache. In the emergency department, his initial blood pressure reading while sitting was 130/60 mm Hg, with a pulse rate of 67/min; the corresponding values while standing were 90/50 mm Hg and 58/min. An echocardiogram showed an ejection fraction of 65% and an aortic valve area of 1.7 cm². Results of computed tomography of the head were unremarkable. Mr Y was sent home but continued to feel dizzy. Dr C subsequently stopped the lisinopril and reduced the dose of metoprolol. The dizziness resolved.

The fall in July 2008 exacerbated Mr Y’s left hip pain. In November he underwent removal of his left hip fixation plate and screws and restarted PT. The dose of vitamin D was increased to 800 IU daily. He had no further falls.

Mr Y denied that his falls were a significant problem. He declined a paid attendant or referral to adult day care but agreed to a personal emergency response system when it was explained that this would give his daughter peace of mind.

A Care of the Aging Patient series editor interviewed Mr Y; Ms Y, his daughter; and Dr C in early 2009.

PERSPECTIVES

Mr Y: I’ll be 90 this year . . . [my daughter] invited me to live with her. . . . I’ve fallen a couple of times. When you get old, your equilibrium doesn’t work as good. . . . It was a big worry of my daughter and my doctors.

Dr C: He was on a lot of different medications and was having a lot of pain . . . a lot of medical issues . . .

Ms Y: He was in a skilled nursing facility recuperating from his hip fracture when they diagnosed him with dementia and told him he couldn’t live alone. We had meetings with the doctors, social workers, and therapists. He wanted to go back and live alone, but I said, ‘I’m a very good gait therapist and I can help you walk better’. . . . I told him that it would be more of a burden . . . to be too far away . . .

Falling can cause lasting discomfort and decreased function, imposing family and societal care burdens. While evidence indicates that assessment and intervention can reduce the risk of falls and injuries, often these interventions require trade-offs between health conditions and between the patient’s desire for independence and safety concerns.

PREVALENCE, CONSEQUENCES, AND ETIOLOGY OF FALLS

Table 1. Independent Risk Factors for Falling Among Community-Living Older Adults

More than one-third of community-living adults older than 65 years fall each year.6-11 Approximately 10% of falls result in a major injury such as a fracture, serious soft tissue injury, or traumatic brain injury.6-13 Injury rates are similar for elderly men and women and for African Americans and whites, although women are more likely to experience fractures, and men and African Americans are more likely to experience traumatic brain injuries.6,11-13 Inability to rise without help, experienced by half of older persons after at least 1 fall, may result in dehydration, pressure ulcers, and rhabdomyolysis.13

Falls are major contributors to functional decline and health care utilization. Falling without a serious injury increases the risk of skilled nursing facility placement by 3-fold after accounting for cognitive, psychological, social, functional, and medical factors; a serious fall injury increases the risk 10-fold.14 Falls and fall injuries are among the most common causes of decline in the ability to care for oneself and to participate in social and physical activities.17,18 Diminished self-confidence may partially explain functional loss following falls without serious injury.

As with other conditions affecting older adults, such as delirium and urinary incontinence, falling is classified as a geriatric syndrome. Defining features of geriatric syndromes include the contribution of multiple factors and the interaction between chronic predisposing diseases and impairments and

©2010 American Medical Association. All rights reserved.
Box. Mobility Screen and Balance and Gait Evaluation

Get Up and Go Test. The most frequently recommended screening test for mobility, this test takes less than 1 minute. Have the patient get up from a chair, walk 10 feet, turn, return to the chair, and sit down. Any unsafe or ineffective movement suggests balance or gait impairment and increased risk of falling, and the patient should be referred to physical therapy for complete evaluation and treatment.

(Mr Y was very slow and unsteady getting out of the chair; he had flexed posture and a slow, shuffling gait.)

A person who fails this quick mobility screen should have a more complete balance or gait evaluation by a physician or a physical or occupational therapist. An example:

Performance-Oriented Mobility Assessment (POMA). The POMA involves assessing the quality of transfer, balance, and gait maneuvers used during daily activities and takes about 5 to 10 minutes to complete. The POMA is not appropriate for very functional patients or patients with a single disabling disease such as Parkinson disease or stroke. While there are several versions of the POMA, one feasible in a busy ambulatory setting includes observing these transfer and balance maneuvers: get up from chair; perform side-by-side, 1-leg, and tandem (one foot in front of the other) stands (5-10 seconds each); turn in circle; sit down; and assessment of these gait components while the patient walks 10 feet and turns: gait initiation; heel-toe sequencing; step length, height, and symmetry; path deviation; walk stance (how far feet are apart while walking); steadiness on turning; arm swing; neck, trunk, hip, and knee flexion.

In addition to determining if the patient is at risk of falling, the POMA can be used to ascertain if there are balance and gait impairments that require intervention (eg, cane or walker) and to assess for the presence of possible neurological or musculoskeletal disorders. For example, difficulty getting up without arms suggests proximal muscle weakness; difficulty with gait initiation suggests fronto-subcortical disorders such as Parkinson disease or normal-pressure hydrocephalus; worse performance with eyes closed than open suggests peripheral neuropathy or vestibular problem; wide-based gait that worsens with eyes closed and improves with handheld assist suggests peripheral neuropathy; leg crossing the midline suggests central nervous system disorder such as stroke or normal-pressure hydrocephalus; shorter step with one leg suggests a muscle, joint, or nervous system problem on the opposite side.

A version of the POMA, with scoring, can be found at http://www.geriatricsatyourfingertips.org/ebook/gayf_36.asp#c36s7_PERFORMANCE-ORIENTED_MOBILITY_ASSESSMENT_POMA.

Copies of the assessment with instructions and scoring can also be obtained from the author.

THE EVIDENCE: RISK FACTORS AND PREVENTION

Methods

We conducted 3 systematic reviews, focused on community-living older adults, to identify (1) multiple impairments and conditions predisposing to falls; (2) effective physical therapy and exercise interventions; and (3) effective multifactorial interventions. The search strategies, search results, and publications resulting from each search are presented in the eAppendix, available at http://www.jama.com.

Risk Factors for Falling

The factors identified in the systematic review as contributing independently to risk of falling or experiencing a fall injury in at least 2 of the 33 studies appear in Table 1. The strongest risk factors for falling include previous falls; strength, gait, and balance impairments; and use of specific medications. Of note, falls and fractures share many risk factors.

The risk of falling increases with the number of risk factors. In 1 study, the 1-year risk of falling increased from 8% to 19% to 32% to 60% to 78% (χ² for order in proportions, 62.7; P < .001) as the number of factors increased from 0 to 4 or more, suggesting that the presence of the factors listed in Table 1 can be used to both estimate an individual’s risk of falling and to guide prevention efforts.

Medications are particularly complex risk factors for falling. Diseases such as depression, heart failure, or hypertension may increase fall risk but so also may the medications used to treat them. Common adverse medication effects such as unsteadiness, impaired alertness, and dizziness are risk factors for falling. The risk of falling among older adults increases with the number of medications consumed, independent of medication indications and other confounders. Psychoactive medications (sedatives, antipsychotics, and antidepressants), anticonvulsants, and antihypertensive medications are most strongly linked to increased risk for falling.

INTERVENTIONS TO PREVENT FALLS

Single as well as multifactorial interventions have been investigated in randomized controlled trials. Single interventions evaluated include cardiac pacing, vision improvement, home safety modifications, medication reduction, and PT or exercise.

Single Interventions

The 1 trial of cardiac pacing in persons with cardioinhibitory carotid sinus hypersensitivity who had fallen was associated with a reduced rate of falling (relative risk [RR], 0.42; 95% confidence interval [CI], 0.23-0.75 [N = 171]). Expedited first cataract surgery significantly reduced falls (RR, 0.60; 95% CI, 0.36-0.98 [N = 306 women]).
surgery showed no benefit. A multicomponent vision intervention trial including treatment of glaucoma, referral for cataract surgery, and new refraction was associated with a nonsignificant increased risk of falling (RR, 1.74; 95% CI, 0.97-3.11 [N = 616]). Home safety modification was not effective as the sole intervention among participants not selected for fall risk (RR, 0.90; 95% CI, 0.79-1.03 [2367 participants, 3 trials]). However, those with previous falls or fall risk factors did benefit (RR, 0.56; 95% CI, 0.42-0.76 [491 participants, 2 trials]). Evidence is insufficient to determine the role of cardiac pacing in fall prevention but does support first cataract surgery and home safety modifications in at-risk individuals.

Reducing the number of medications consumed was associated with a reduction in fall risk in 1 trial, although efforts to reduce psychoactive medications were not effective. In another randomized controlled trial, psychoactive medication withdrawal resulted in a 66% reduction in rate of falling (RR, 0.34; 95% CI, 0.16-0.73 [N = 93]), although individuals resumed the medications after the trial. A multicomponent medication strategy including academic detailing and feedback to clinicians and medication modification by clinicians resulted in a 39% reduction in falls (95% CI, 9%-59% [N = 659]). Medication reduction appears effective, although withdrawal of psychoactive medications proved difficult.

Exercise is the most widely studied single intervention. Twenty-five trials of either tai chi (6 trials) or combinations of strength, gait, balance, and endurance training (19 trials) were identified in the systematic review (eAppendix). The rate of falling declined a relative 25% to 33% in the 4 of 6 tai chi trials that showed a significant difference. Nine of 14 trials of combination training showed significant relative reductions ranging from 22% to 46%. All of the positive trials included balance training as one component. Only 1 of 5 trials of a single exercise component reduced falls. The frequency and intensity of the exercise programs varied among the effective trials. Evidence supports progressive balance and strength, and perhaps endurance, training for fall prevention, although the optimal frequency and intensity remain to be determined.

Multifactorial Fall Prevention
Multifactorial trials included those in which investigators carried out the intervention components or directly ensured that the interventions occurred and those in which investigators only offered advice or referral to existing community or health care sources. Among the former group with direct interventions, at least 1 fall-related outcome was better in the intervention group than in the control group in 8 of 11 trials (Table 2). Among the latter group with advice/referral only, none of the 14 trials found a benefit.

Other systematic reviews and meta-analyses have drawn conflicting conclusions about the effectiveness of multifactorial interventions. Campbell and Robertson concluded that multifactorial interventions were no more effective than single interventions such as PT, while Chang et al found the multifactorial approach superior. Gates et al and the Cochrane review both concluded that multifactorial interventions that actively provide treatments are more effective than those that provide only knowledge and referral. Most of the effective trials included multiple factor risk assessment, PT or exercise, withdrawal or minimization of psychoactive and other medications, and home safety modification. Components included in the clinical trials are listed in the eTable. The preponderance of evidence supports multifactorial interventions as the most effective preventive strategy.

Fall Prevention Strategies in Cognitively Impaired Patients
The only study of cognitively impaired community-living older adults (274 individuals presenting to an emergency department after a fall) showed no significant difference between the intervention group, which received management of medical problems, modification of psychotropic medications, PT, and home hazard modification, and the control group (RR, 0.92; 95% CI, 0.81-1.05). Conversely, while Mahoney et al found no intervention effect overall, among patients with a Mini-Mental State Examination score of 27 or less, those in the intervention group had a lower rate of falls than controls (RR, 0.55; P = .05). The effectiveness of fall prevention in cognitively impaired older adults remains unknown.

Prevention of Fractures in Men
The eBox lists risk factors for osteoporosis and fractures, recommendations for screening, and evidence for treatment and prevention, in older men. No consensus exists regarding screening in older men. At least 800 IU of vitamin D is the only medication with compelling evidence of effectiveness for fracture prevention in older men.

TRANSLATING EVIDENCE INTO CLINICAL PRACTICE
Screening
Ms Y: I know my Dad only tells people what he wants them to know . . . like why he was falling before he came to live with me; there was alcohol involved and nobody knew that but him and me . . . .

The first clinical issue is deciding who should have risk factors for falling assessed and treated. Evidence suggests that persons older than 65 years who present with a fall, report at least 1 injurious fall or 2 or more noninjurious falls, or report or display unsteady gait or balance (Box) should undergo fall risk factor assessment and management. If patients report no more than 1 noninjurious fall and have no difficulty with walking or balance, no further assessment is needed. The American Geriatrics Society guideline recommends this screen at least yearly. For patients with cognitive impairment, caregivers should be queried.

Assessing and Managing Fall Risk Factors
Dr C: We went problem by problem and came up with a plan to reduce his risk of falling . . . He’s been a very good illustration of things you can do that make a difference.

We attacked the muscle weakness by having him go through extensive physical therapy and making sure he has the

Abbreviations: AOR, adjusted odds ratio; CI, confidence interval; ED, emergency department; HMO, health maintenance organization; HR, hazard ratio; IRR, incident rate ratio; NA, not available; NR, not reported; NS, not significant; OR, odds ratio; RR, relative risk.

bIncludes only trials that evaluated at least 3 risk factors identified in the first search (Table 1) and that enrolled only community-living participants with known cognitive impairment. Follow-up was 12 months unless stated otherwise.

cAll results are for the intervention group relative to the control group.

dUsed a factorial design with 7 intervention groups. Only the full multifactorial intervention and control groups are included here. Total N = 1107 in all groups.

eAdditional primary care group (risk factor assessment plus referral back to primary care physicians) was not effective (primary care referral relative to control: OR, 1.17; 95% CI, 0.57-2.37).

fCommunity sites and physicians may not have had the training or ability to complete the interventions; there was no assurance that participant or physician followed up on recommendations.

References are included in the eAppendix.

*Level of evidence based on the results of authors’ 3 systematic reviews (eAppendix): class Ia, evidence from at least 2 randomized controlled trials; Ib, evidence from 1 randomized controlled trial or meta-analysis of randomized controlled trials; II, evidence from at least 1 nonrandomized controlled trial or quasi-experimental study; III, evidence from prospective cohort study (risk factor for falls); IV, based on expert committee opinion or clinical experience in absence of other evidence. All management recommendations also meet the criteria of ease of implementation and clinical importance.
appropriate assistive devices . . . [we did] a home safety evaluation. . . . We started him on calcium and vitamin D . . .

The multifactorial nature of fall prevention means that care must be coordinated among physicians, nurses, physical therapists, and occupational therapists. A primary care clinician can coordinate care by assessing and managing the medical components and referring patients to home care or outpatient rehabilitation. Alternatively, interdisciplinary fall teams or clinics are available at many geriatric or rehabilitation centers. Regardless of location or disciplines involved, effective fall prevention requires assessing potential risk factors, managing the risk factors identified, and ensuring that the interventions are completed. Potential trade-offs must be considered in formulating the assessment and management strategy.

Assessing the Risk Factors
Assessment should focus on determining the circumstances of previous falls and on identifying risk factors or factors known to be the target of effective interventions (Table 1 and Table 3). The assessments of fall risk listed in Table 3 should be completed in all older patients at risk. Factors increasing Mr Y’s risk of recurrent falls include past falls; cognitive, strength, gait, and balance impairments; ADL limitations; macular degeneration; pain; postural hypotension; mild aortic stenosis; alcohol (in his earlier falls); and several of his medications, specifically metoprolol, lisinopril, hydrochlorothiazide, nitroglycerin, hydrocodone, and diphenhydramine (Table 3). A decreased vitamin D level (17.9 ng/mL), which should be suspected with muscle pain or weakness, fractures, or decreased sun exposure, could also have contributed.

The examination should include cognitive evaluation, postural blood pressure measurement, cardiac rhythm and rate, muscle strength, joint range of motion, and examination of the feet and proprioception (Table 3). A balance and gait screen or evaluation should also be performed (Box).

Mr Y’s abnormal clock drawing (eFigure) indicates executive dysfunction that can occur with intact memory, as with Mr Y.29 Like Mr Y, individuals with executive dysfunction may have difficulty with instrumental ADL (Table 1) and may manifest slow gait and other gait impairments.30 This combination of cognitive and gait impairments can be seen in subcortical degenerative disorders such as normal-pressure hydrocephalus (not evident on Mr Y’s magnetic resonance imaging scan) or subcortical vascular dementia.31

MANAGING THE RISK FACTORS IDENTIFIED
The evidence suggests that improving as many of the factors listed in Table 3 as possible is the most effective way to reduce the risk of falling. Medication reduction, physical therapy, and home safety modifications have the strongest evidence of benefit for fall prevention in clinical practice.

Dr C: I took off a lot of blood pressure medications because he was feeling dizzy and his pressure was low. . . . We need to make sure that we control the pain, because if you have severe pain . . . you get deconditioned and you fall. On the other hand, the more medications you take, you run the risk of getting more confused . . . it increases the risk that . . . he might fall. . . .

Medications
Dizziness or lightheadedness on standing or the use of 4 or more medications should prompt the measurement of postural blood pressure and reduction in the number and dosages of medications. Particular attention should be given to the possible elimination or dose reduction of medications known to increase orthostasis or fall risk (Table 3).

The presence of multiple health conditions necessitates a consideration of trade-offs between benefits vs risks of medications, particularly when the treatment of one condition may worsen another.32 Antihypertensive, anticoagulant, and antidepressant medications commonly pose such trade-offs for patients at risk for falling. Few data currently exist to guide decision-making for these trade-offs. The clinician must consider which condition presents the greatest threat to the outcome priority of greatest importance to the patient.33 By eliminating unnecessary medications and reducing the dose of necessary medications, it is often possible to treat coexisting conditions while minimizing risk of medication-related fall or injury.

Dr C articulated well the trade-off between pain management and fall risk for Mr Y. Because pain is a risk factor for falling,34 appropriate treatment may reduce fall risk. Pain assessments result in improved detection and treatment. The American Geriatrics Society pain management guideline provides strategies for older adults (Resources, available at http://www.jama.com).

Adding vitamin D, 800 IU and probably without calcium, is indicated in patients such as Mr Y, who are deficient.35

PHYSICAL THERAPY AND HOME SAFETY MODIFICATION
Mr Y: My doctor and my daughter . . . decided [an emergency alert necklace] would be good . . . and it is. It’s a 24-hour-a-day watchdog. It’s very simple to use . . . I have a fixture in the bathtub with handrails and seats. . . . I haven’t had any missteps . . . since I started it.

Ms Y: When he had the [hip] hardware removed, I requested [physical] therapy again. . . .

Home safety evaluations and modifications, as described in Table 3, can be self-conducted (Resources) or performed by a nurse, physical therapist, or occupational therapist. Patients with reported or observed balance or walking problems should be referred for PT. If homebound, a patient is eligible for treatment by a Medicare-certified home care agency if progress is documented. Treatment at home allows assessment and management of mobility in the patient’s own environment. If not homebound, then the patient must be referred to outpatient rehabilitation, and the therapist must rely on self- or family-report of home safety issues. Available evidence suggests that, for fall prevention, PT should consist of progressive standing balance and strength exercises; transfer practice; gait interventions, including evaluation for an assis-
tive device (cane or walker); and instructions in techniques for arising after a fall. Referral should be made to therapists skilled in evidence-based progressive balance training for older patients (Resources). Endurance training, such as walking, should be added when safe. A challenge is that ongoing exercise is needed to maintain improvements after therapy ends. In addition to recommending walking, referral to community programs targeting older adults should be considered (Area Agencies of Aging may have this information). There is insufficient evidence to determine if PT is beneficial for patients with dementia.\textsuperscript{30} Strategies used by therapists with patients with dementia include simple, repetitive routines; removal of environmental hazards; easy-to-read instructions with pictures; and caregiver involvement.

Occupational therapy for community-dwelling at-risk older adults focuses on safe ADL functioning; upper-extremity function; activity tolerance; and mobility.\textsuperscript{37} Occupational therapists provide patient and family education and prescribe adaptive devices (Table 3). For patients with dementia, occupational therapists counsel caregivers about strategies for safe functioning.

SAFETY VS INDEPENDENCE

Ms Y: I’m a physical therapist, so safety is my job. He does everything the least safe, worst way possible! I’m trying to learn to choose my battles . . .

Persons at risk for falling face trade-offs between safety and functional independence. To reduce fall risk, they may have to avoid desired activities or rely on help. Conversely, patients may have to accept risk of serious injury if they wish to continue performing activities beyond their balance capability. For individuals who are cognitively intact, the clinician’s responsibility is to present the evidence, attempt to minimize risk through proven assessment and management strategies, and ensure an informed decision. If there is any question, the clinician must ascertain whether the individual has the capacity to make informed decisions, either by interviewing the patient and family or by referring the patient to a psychiatrist or geriatrician.

For the individual with reduced decisional capacity, the clinician must work with the family or caretakers, as did Dr C and Mr Y’s daughter. As she has done, Mr Y’s daughter needs to take the initiative. As was evident with Mr Y and his daughter, the family may prioritize safety while the patient values independence and mobility. Negotiations are often needed to get the family to agree, and the patient to assent, to a balance between safety and independence.

Support for Caregivers

Ms Y: Living with someone with dementia—is tremendously stressful. I had no idea that I would be this impatient sometimes. I have a group of women I know from taking a class on caregiving, and we try to support each other. It’s been rough, but it’s been a real gift in terms of getting to know my dad.

Dr C: I wanted to know what would help her [daughter] not get burnt out and to try to provide her with more services . . . we’ve talked about respite programs . . . We’ve offered home health aides and other kinds of home support.

Cognitively intact older adults who fall may handle their own health and functional needs. Among community-dwelling frail or cognitively impaired older adults, however, falls further increase caregiver burden.\textsuperscript{39} As Dr C elicited from Ms Y, primary caregivers of cognitively and functionally impaired elders often experience stress, which can be uncovered through a brief private interview with the caregiver or by use of self-administered instruments.\textsuperscript{39} Caregivers with high levels of stress should be referred to social agencies or support groups. Local Area Agencies on Aging (Resources) can provide information on sources of help and financial assistance. Geriatric care managers are another source of assistance, although neither health insurance nor long-term care insurance usually covers this cost.

Challenges to Incorporating Fall Prevention Into Practice

Some challenges to incorporating fall prevention into practice, such as time constraints, competing demands, and inadequate reimbursement, are similar to those facing other cognitive services.\textsuperscript{60-62} Other barriers, such as perceived lack of skills in managing complex, multifactorial health conditions, and lack of coordination across disciplines and settings, are particularly acute for geriatric syndromes.

CONCLUSIONS

With the use of screening tools, consideration of trade-offs between competing conditions, and reliance on other members of the health care team, evidence-based fall risk assessment and management is feasible and effective. Because the factors contributing to falls affect important health outcomes such as symptom burden and function, fall prevention strategies bestow multiple health benefits. Dr C, working with Mr Y’s daughter, demonstrated the feasibility and effectiveness of incorporating fall prevention strategies into clinical practice.

Author Contributions: Dr Tinetti had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis. Financial Disclosures: None reported. Funding/Support: This study was supported in part by the Claude D. Pepper Older Americans Independence Center at Yale School of Medicine (P30AG21342), from the National Institute on Aging. The Care of the Aging Patient series is made possible by funding from The SCAN Foundation. Role of the Sponsor: The funders had no role in the collection, management, analysis, and interpretation of the data or the preparation, review, or approval of the manuscript.

Online-Only Material: A list of relevant Web sites (Resources) and the eFigure, eAppendix, eTable, and eBox are available at http://www.jama.com.

Additional Contributions: We thank the patient, his family, and his physician for sharing their stories and providing permission to publish them.

WEB LINKS FOR PATIENTS AND FAMILIES
NIHSeniorHealth: Falls and Older Adults
http://nihseniorhealth.gov/falls/toc.html
This site, created jointly by the National Institute on Aging, the National Library of Medicine, and the US Department of Health & Human Services, provides well-researched and practical information on falls and fall prevention.

Tips for Older Adults and Their Loved Ones
http://www.healthinaging.org/public_education/falls_tips.php
This site offers helpful tips to older adults or those caring for older adults on how to reduce the risk of falling.

Falls—Older Adults
http://www.cdc.gov/ncipc/duip/preventadultfalls.htm
This site, maintained by the Centers for Disease Control and Prevention (CDC), includes helpful suggestions on fall prevention strategies. The site also provides a link to the CDC Home Fall Prevention Checklist for Older Adults.

National Association of Area Agencies on Aging (n4a)
http://www.n4a.org
This site describes the resources available through the Area Agency on Aging. The telephone number for the local Area Agency on Aging is in the white pages of your telephone book, under “Area Agency on Aging” or “Senior Services.” If you cannot find the phone number in those places, call your State Office on Aging, which is listed in the blue pages of your phone book, in the “State Services” section.

National Family Caregivers Association
http://www.nfcacares.org
This site offers a virtual library of information and educational materials ranging from national education campaigns to tips and tools for family caregivers. It provides information on agencies and organizations that provide caregiver support.

Eldercare
http://www.healthinaging.org/public_education/eldercare/
This site provides a free, printable version of the Eldercare at Home guide prepared by the Foundation on Aging (FHA). Authored by more than 30 experts in geriatric care, this free, comprehensive 27-chapter online guide for family caregivers offers a problem-solving approach to managing the most common problems faced in caring for older adults at home and offers suggestions for working cooperatively with clinicians.

Caregiver Burnout
http://www.healthinaging.org/public_education/caregiver_burnout.php
This site provides information on asking for assistance and taking care of oneself.

WEB LINKS FOR CLINICIANS
American Geriatrics Society (AGS) Clinical Practice Guideline
http://www.americangeriatrics.org/education/cp_index.shtml
This is the newly released AGS evidence-based fall prevention guideline. This guideline presents an evidence-based algorithm describing who should be screened for falls and which assessments and interventions should be considered for patients who screen in at risk for falling.

Compendium Preventing Falls: What Works: A CDC Compendium of Effective Community-Based Interventions From Around the World
http://www.cdc.gov/HomeandRecreationalSafety/Falls/preventfalls.html#
This is the updated AGS Clinical Practice Guideline: Pharmacological Management of Persistent Pain in Older Persons. The recommendations represent the consensus of a panel of pain experts and were derived from a synthesis of the literature combined with clinical experience in caring for older adults with persistent pain. In addition to recommendations for class and dose of medications to use for pain of varying severity and etiology, the site includes a tip sheet for older adults and a list of additional public education resources.

Management in Primary Practice
http://www.americangeriatrics.org/education/falls.shtml
This site provides user-friendly tools for assessing and managing fall risk that were developed for use in primary care. There are tools for the clinician as well as educational materials for patients. This site also provides several helpful links that provide further information and materials for fall prevention in practice.

Home and Recreational Safety

**TINETTI ASSESSMENT TOOL**

**Balance Tests**

**Initial Instructions:** Subject is seated in hard, armless chair.
The following maneuvers are tested.

1. **Sitting balance**
   - Leans or slides in chair = 0
   - Steady, safe = 1

2. **Arisers**
   - Unable without help = 0
   - Able, uses arms to help = 1
   - Able without using arms = 2

3. **Attempts to arise**
   - Unable without help = 0
   - Able, requires more than 1 attempt = 1
   - Able to arise, 1 attempt = 2

4. **Immediate standing balance**
   - (first five seconds)
   - Unsteady (swaggers, moves feet, trunk sway) = 0
   - Steady but uses walker or other support = 1
   - Steady without walker or other support = 2

5. **Standing balance**
   - Unsteady = 0
   - Steady, but wide stance (medial heels more than 4 inches apart) and uses cane or other support = 1
   - Narrow stance without support = 2

**Scoring Key:**
- Balance Score: _______/16 24 or above = low risk of falling
- Gait Score: _______/12 20-24 = moderate risk of falling
- Balance + Gait Score: _______/28 19 or below = high risk of falling

**6. Nudged** (subject at maximum position with feet as close together as possible, examiner pushes lightly on subject's sternum with palm of hand 3 times)

**7. Eyes closed** (at maximum position #6)

**8. Turning 360 degrees**
- Discontinuous steps = 0
- Continuous = 1
- Unsteady (grabs, staggers) = 0
- Steady = 1

**9. Sitting down**
- Unsafe (misjudged distance, falls into chair) = 0
- Uses arms or not a smooth motion = 1
- Safe, smooth motion = 2

**10. Initiation of gait** (immediately after told to "go")
- Any hesitancy or multiple attempts = 0
- To start = 1
- No hesitancy = 1

**11. Step length and height**
- Right swing foot does not pass left stance foot with step = 0
- Passes left stance foot = 1
- Right foot does not clear floor completely with step = 0
- Completely clears floor = 1
- Left swing foot does not pass right stance foot with step = 0
- Passes right stance foot = 1
- Left foot does not clear floor completely with step = 0
- Completely clears floor = 1

**12. Step Symmetry**
- Right & left step length not equal = 0
- Right & left step appears equal = 1

**13. Step Continuity**
- Stopping or discontinuity between steps = 0
- Steps appear continuous = 1

**14. Path** (estimated in relation to floor tiles, 12" diameter, observe in excursion of 1 foot over about 10 feet of the course)
- Marked deviation = 0
- Mild/moderate deviation or uses walking aid = 1
- Straight without walking aid = 2

**15. Trunk**
- Marked sway or uses walking aid = 0
- No sway but flexion of knees, or back, or spreads arms out while walking = 1
- No sway, no flexion, no use of arms, and no use of walking aid = 2

**16. Walking**
- Heels apart = 0
- Heels almost touching while walking = 1

- **PARTIAL FULLERTON ADVANCED BALANCE (FAB) SCALE**

**SCORE:**

1. Reach forward to retrieve an object (pencil) held at shoulder height with outstretched arms.
   - 0 Unable to reach the pencil without taking more than two steps.
   - 1 Able to reach the pencil but needs to take two steps.
   - 2 Able to reach the pencil but needs to take one step.
   - 3 Can reach the pencil without moving the feet but requires supervision.
   - 4 Can reach the pencil safely and independently without moving the feet.

2. **Walk with head turns.**
   - 0 Unable to walk 10 steps independently while maintaining 30 degree head turns at an established pace.
   - 1 Able to walk 10 steps independently but unable to complete required number of 30 degree head turns at an established pace.
   - 2 Able to walk 10 steps but veers from a straight line while performing 30 degree head turns at an established pace.
   - 3 Able to walk 10 steps in a straight line while performing 30 degree head turns at an established pace but head turns less than 30 degree in one or both directions.
   - 4 Able to walk 10 steps in a straight line while performing required number of 30 degree head turns at established pace.

Getting Up From a Fall

After you fall, panic is often your first reaction. However, how you react after a fall can cause more injuries than the fall itself. If you try to get up too quickly or in the wrong position you may make an injury worse.

Remember to take several deep breaths, assess the situation and determine if you are hurt. If you believe you are injured, do not attempt to get up. Instead, call 911 or get help from a family member. But if you feel strong enough to get up, follow these steps provided by the American Academy of Orthopedic Surgeons.

1) Try to fall on your side or buttocks. Roll over naturally, turning your head in the direction of the roll.

2) If you can, crawl to strong, stable furniture like a chair, and pull yourself up. Approach the chair from the front and put both hands on the seat.

3) Slowly, begin to rise. Bend whichever knee is stronger, keep your other knee on the floor.

4) Slowly twist around and sit in the chair.

Mindfulness in Fall Prevention

→ Bring your attention to how your body is feeling before, during, and after changing position; for example, from lying down to sitting or from sitting to standing. Ask yourself “How is my body feeling right now? Am I dizzy or light headed? Do I feel pain or weakness in some part of my body?”

→ While walking, pay attention to the act of walking. Try to focus only on the walking. Our minds are easily distracted which can increase the potential for falls.

→ Slow down. During every daily task, try to bring attention to the task at hand rather than allowing your thoughts to move onto something else.

→ Use your breath, the sensation, and awareness of your breath to keep your attention in the present moment. You may need to repeat this many times until it becomes a habit.

→ Use everyday objects and events to help you bring your attention back to the present moment. For example, noticing the sound of a phone ringing, checking the time, or seeing a red traffic light are great examples that can help you to bring your attention back to the present moment.

**Home Assessment Recommendations:**

- [ ] Grab bars
- [ ] Eliminate clutter
- [ ] Rugs
- [ ] Lighting
- [ ] Stairs
- [ ] Adaptive equipment

Signature/Title: ___________________________ Date: ___________________________
Why 5?

1. **Strength**- Muscle loss starts early (25-30). Less muscle means weaker bones (not a direct risk for a fall but more to injury) and of course lack of strength to do daily activities. A simple act like getting up from a chair can become difficult. You must do some type of weight bearing exercise to build muscles and strength.

2. **Balance**- Aging causes complications to balance. Many body components work together to keep you upright. Without practicing your balance it can become poor and your chance of falling will increase.

3. **Flexibility**- Stiffness in muscles occurs from lack of use or overuse without gentle stretching. Lack of flexibility, especially in your ankles and hips can lead to a fall as well as lead to poor posture.

4. **Endurance**- This can be as simple as how long you can stand on your feet without getting tired. Exercise can increase your stamina. Increased stamina decreases your risk for falling. You will also have more energy!

5. **Mobility/Walking**- Developing strength, improving balance, increasing flexibility, and boosting endurance will help overall mobility and the confidence to walk free from fear of falling. Walking is great overall exercise, but you must include all 5 to be in the best shape to prevent a fall.

**CHECK WITH YOUR HEALTHCARE PROVIDER BEFORE DOING ANY TYPE OF EXERCISE.**
Patient Name: 

Date of Birth: 

MRN: 

☐ Vial of Life provided

☐ Night Light provided for ______ room(s)

Lifeline recommended ☐ Yes ☐ No ☐ Already has home alarm system

Comments: 

☐ Referred for grab bars or other home modifications

☐ Contact with PCP required

☐ Exercise video provided ☐ Recommend Sitting ☐ Standing ☐ No Video Provided because

Other exercises to be done on a regular basis:
